Puohokamo Stream

Puohokamo Stream splits into three main branches at 2,100 ft altitude; the longest is the middle branch that is headed at 4,400 ft altitude 6.4 mi inland (plate 1). The stream rises steeply from sea level to 600 ft altitude 0.6 mi from the coast (a gradient of 930 ft/mi) and at this altitude the stream valley is incised 200 ft below the upland surface. With the exception of 3,000 ft of Honomanu Basalt at the coast, this stream lies on lava flows of the Kula Volcanics along most of its length (Stearns and Macdonald, 1942). Streamflow is captured by five of the surface-water diversion systems (table 4).

Puohokamo Stream was never dry during 1913–71 at gaging station 5450 at 1,322 ft altitude (table 2, plate 1). At the gaging stations at about 2,800 ft altitude on the three stream branches, streamflow was perennial in the west (station 5440) and middle (station 5430) branches but went dry in the shorter east (station 5420) branch during 1919–27 when the gaging stations were operated concurrently. Base-flow estimates from long-term streamflow records indicate that the average annual gains from ground water are about 5.46 Mgal/d upstream of 1,322 ft altitude, 2.8 Mgal/d of this flow is gained downstream of 2,800 ft altitude (table 2, fig. 15I).

Several sets of streamflow measurements in sections of the stream branches also show continuous streamflow gains upstream of 1,300 ft altitude (table 12). Measurements were made some time in the 1920's between 2,050 and 1,300 ft altitude that show a gain of about 0.6 Mgal/d (written commun. from J.H. Hofmann to J.H. Foss, November 17, 1932 in USGS Hawaii District files). Streamflow data from February 3, 1920 confirm this pattern (table 12). Measurements were also made on October 29–30, 1932 and June 12, 1933 between 2,900 ft and 2,400 ft altitude during base-flow conditions that show gains of about 0.1 Mgal/d in the east and west branches and a slight loss of about 0.05 Mgal/d in the middle branch (Hofmann, 1934). The latter measurement represents only a 15 percent difference between the upstream and downstream measurements; therefore, this value is probably about the same magnitude as the measurement error inherent in the method used in that particular study. Four measurements were made on April 10, 1962, three on the middle branch

between 3,200 ft and 2,900 ft altitude and one on the west branch at 2,850 ft altitude (U.S. Geological Survey, undated [a]). These measurements show a gain of about 0.2 Mgal/d in the middle branch. A measurement made in March 1928 by EMI shows a gain of about 0.1 Mgal/d between 900 ft and 500 ft altitude (table 10). No measurements were made where the stream flows over the Honomanu Basalt. No water budget was calculated for the Puohokamo Stream subbasin.

Streamflow

Estimates of streamflow and base flow are based on streamflow records of varying length and from different times. The error associated with comparing these records is not considered significant because the average annual values used in the comparisons are expected to be within about 10 percent of the true value in most cases. A statistical analysis of five streamflow records, each with more than 60 years of record, shows that the average annual discharge for any 10-year period within that record has a standard error of 12 percent when compared with the whole record (Fontaine, 1996). When the length of the subset is increased to a 50-year period, the standard error only improves to 5 percent. Thirty nine of the streamflow records for the study area are equal to or greater than 10 years long.

For this study, the length of the period of record at each gaging station was determined to be unimportant by comparing each record to three reference records from the study area. The three longest streamflow records, 5080 (73 years), 5180 (76 years), and 5870 (85 years) were chosen as reference records. For each other individual record, a time period equal to the length of that record was chosen. A subset of a reference record was then selected from this same time period and the average flow during that time period was compared with the total reference record to estimate the ratio of flow during the subset period to the reference period. This analysis was made for all three reference records and the result was averaged to obtain a period-of-record scale factor for each of the other records. The scale factor ranged from 0.88 to 1.13 (table 2). This variability is consistent with the statistical analysis reported by Fontaine (1996). This range of accuracy is considered sufficient for the type of comparisons made in this study, and therefore, no corrections were made to any of the records to account for differences in length or period of record.

DURATION DATA VALUES ARE INTERPOLATED FROM DURATION TABLE:

DATA ARE NOT ANALYTICALLY FITTED TO A PARTICULAR STATISTICAL DISTRIBUTION,
AND THE USER IS RESPONSIBLE FOR ASSESSMENT AND INTERPRETATION.

ADDITIONAL CONDITIONS FOR THIS RUN ARE:

STATISTICS ARE BASED ON LOGARITHMS (BASE 10).
NUMBER OF VALUES IS REDUCED FOR EACH NEAR-ZERO OR ZERO VALUE.

DURATION DATA VALUES ARE INTERPOLATED FROM DURATION TABLE:

DATA ARE NOT ANALYTICALLY FITTED TO A PARTICULAR STATISTICAL DISTRIBUTION,
AND THE USER IS RESPONSIBLE FOR ASSESSMENT AND INTERPRETATION.

ADDITIONAL CONDITIONS FOR THIS RUN ARE:

STATISTICS ARE BASED ON LOGARITHMS (BASE 10).
NUMBER OF VALUES IS REDUCED FOR EACH NEAR-ZERO OR ZERO VALUE.

NUMBER OF VALUES = 19 (NUMBER OF NEAR-ZERO VALUES = 0)

DURATION DATA VALUES ARE INTERPOLATED FROM DURATION TABLE:
DATA ARE NOT ANALYTICALLY FITTED TO A PARTICULAR STATISTICAL DISTRIBUTION,

AND THE USER IS RESPONSIBLE FOR ASSESSMENT AND INTERPRETATION.

ADDITIONAL CONDITIONS FOR THIS RUN ARE:

STATISTICS ARE BASED ON LOGARITHMS (BASE 10).
NUMBER OF VALUES IS REDUCED FOR EACH NEAR-ZERO OR ZERO VALUE.

NUMBER OF VALUES = 19 (NUMBER OF NEAR-ZERO VALUES = 0)
